Motivation

- Conversation platforms have now become prevalent for both personal and professional usage. (like Fresco and Slack)
- Logs of such conversations offer potentially valuable information for various other applications such as automatic assessment of possible collaborative work among people.
- It is thus vital to invent effective segmentation methods that can separate discussions into small granules of 'independent' conversational snippets.
- By 'independent', we mean a segment should as much as possible be self-contained and discussing the same topic, such that a segment can be suggested if any similar conversation occurs again.

Problem Description

- A chat sequence is represented as: $C = \{c_1, \dots, c_i, \dots, c_{|t|}\}$ where c_i is a text snippet i.e a post.
- A segment or a subsequence can be represented as: $C_{a:b} = \{c_a, \dots, c_b\}$
- A segmentation of C is defined as a segment sequence $S = \{s_1, \dots, s_p\}$ where $s_j = C_{a_j:b_j}$ and $b_j + 1 = a_{j+1}$
- Given an input text sequence C , the segmentation is defined as the task of finding the most probable segment sequence S .

U0ACRBLV says --[1471961263.000550]-=: If the latter, Id suggest the binary builds, or homebrew if on a mac
U0KRS6POU says --[1471961647.000551]-=: Simply run it ... but if I can build it it's a must :smile:
```

The Information Bottleneck

- The information bottleneck method is a technique in information theory introduced by Naftali Tishby, Fernando C. Pereira, and William Bialek. ^[1]
- It is designed for finding the best tradeoff between accuracy and complexity (compression) when summarizing (e.g. clustering) a random variable X , given a joint probability distribution $p(X,Y)$ between X and an observed relevant variable Y .
- The IB objective can be achieved by maximizing:

$$F = I(T, Y) - (1/\beta) * I(X, T)$$

where,

T : The compressed variable after compressing X .

Y : The relevant variable which encapsulate meaningful information about X .

$I(T, Y)$: The mutual Information between T and Y . This information needs to be preserved.

$I(X, T)$: The mutual information between X and T . This needs to be minimum.

IB Inspired Text Segmentation Algorithm

- We propose that a segment sequence S should also contain as much information as possible about R (i.e., maximize $I(R, S)$), constrained by mutual information between S and C (i.e., minimize $I(S, C)$).
- IB objective is to maximize:

where,
$$F = I(R, S) - (1/\beta) * I(S, C)$$

C : Chat sequence

S : Segmentation of C

R : Relevance variable - comprises of informative word clusters (will be explained shortly)

- Precisely, we merge the posts (s_i, s_{i+1}) in a thread such that minimum loss in F occurs.
- The 'loss' in F when merging the posts (s_i, s_{i+1}) is defined as:

$$d(s_i, s_{i+1}) = JSD[p(R|s_i), p(R|s_{i+1})] - 1/\beta * JSD[p(C|s_i), p(C|s_{i+1})]$$

JSD is the Jensen-Shanon divergence between two probability distributions.

- $JSD(P, Q) = 1/2 * KLD(P, M) + 1/2 * KLD(Q, M)$

$$M = (P + Q) / 2$$

Methodology

STEP 1 :

- We model the set of relevance variables R as word clusters estimated by utilizing agglomerative IB based document clustering where posts are treated as relevance variables.^[2]
- Consequently, R comprises of informative word clusters about posts.

For a given thread, we calculate the following:

$$1) P(\text{word}_i | \text{post}_j) = \frac{\text{count}(\text{word}_i) \text{ in post } j}{\# \text{ words in post } j}$$

$$2) P(\text{word}_i, \text{post}_j) = P(\text{word}_i | \text{post}_j) \times P(\text{post}_j)$$

$$3) P(\text{post}_j | \text{word}_i) = \frac{P(\text{word}_i, \text{document}_j)}{P(\text{word}_i)}$$

	$P(\text{post}_1 \text{word})$	$P(\text{post}_2 \text{word})$	$P(\text{post}_m \text{word})$
word ₁				
word ₂				
word ₃				
.				
.				
.				
.				
word _n				

Here every row i is a distribution $P(\text{post} | \text{word}_i)$

Form a matrix which gives δ for every combination of probability distribution $P(\text{post} | \text{word})$

	1	2	...	n
1	0	$\delta_{1 2}$		$\delta_{1 n}$
2	$\delta_{1 2}$	0		$\delta_{2 n}$
3	$\delta_{1 3}$		0	
.				
.				
.				
n-1	$\delta_{1 n-1}$	$\delta_{2 n-1}$		
n	$\delta_{1 n}$	$\delta_{2 n}$		0

δ matrix

STEP 2 :

	P(post ₁ word)	P(post ₂ word)	P(post _n word)
word ₁				
word ₂				
word ₃				
.				
.				
.				
.				
word _n				

Merge words with lowest corresponding value in δ matrix.

After merging {word_i,word_j} and forming a cluster,

We update the following:

$$P(\text{word}_i) = P(\text{word}_i) + P(\text{word}_j)$$

$$P(\text{word}_i, \text{post}) = P(\text{word}_i, \text{post}) + P(\text{word}_j, \text{post})$$

$$P(\text{post}|\text{word}_i) = \frac{P(\text{word}_i, \text{post})}{P(\text{word}_i)}$$

We also update the entries corresponding to i and j row/column in δ matrix

STEP 3 :

After getting K word clusters, we update:

$P(\text{word_cluster}_i, \text{post}_j) = \text{Sum of } P(\text{word}, \text{post}_j) \text{ for all words in cluster } i.$

$P(\text{word_cluster}_i) = \text{Sum of } P(\text{word}) \text{ for all words in cluster } i.$

$$P(\text{word_cluster}_i | \text{post}_j) = \frac{P(\text{word_cluster}_i, \text{post}_j)}{P(\text{post}_j)}$$

STEP 4 :

Similar to step 1, we merge posts with lowest δ between their corresponding conditional word cluster distribution. But this time instead of δ matrix we use δ vector which gives distance between adjacent distributions.

$\delta_{l_1} \delta_{l_2}$	$\delta_{l_2} \delta_{l_3}$	$\delta_{l_3} \delta_{l_4}$	$\delta_{l_{n-1}} \delta_{l_n}$
			..	

	P(word clus ₁ post)	P(word clus ₂ post)	P(word clus _k post)
post ₁				
post ₂				
post ₃				
.				
.				
.				
.				
post _n				

Merge docs with the lowest D_{JS} between corresponding rows (check only between adjacent rows) and keep doing it till the stopping criteria is met to get C word segments.

Stopping Criteria

- The stopping criteria is $SC < \theta$, where:
 - 1) $SC = I(R, S) / I(R, C)$
 - 2) The value of θ is tuned by optimizing the performance over a validation dataset
- The value of SC is expected to decrease due to a relatively large dip in the value of $I(R, S)$ when more dissimilar pairs are merged.
- The inspiration behind this specific computation of SC has come from the fact that it has produced stable results when experimented with a similar task of speaker diarization. [3]

Non Textual Clues^[4]

- We incorporate 2 non-textual clues which seem to be important in the chat scenario:
 - Time between two consecutive posts
 - People mentions within the posts
- The formula for d is then modified to:

$$\bar{d}(s_i, s_{i+1}) = w_1 * d(s_i, s_{i+1}) + w_2 * (c_{a_{i+1}}^t - c_{b_i}^t) + w_3 * \|(s_i^p - s_{i+1}^p)\|$$

where,

$c_{a_{i+1}}^t$: time-stamp of the first post of segment s_{i+1}

$c_{b_i}^t$: time-stamp of the last post of segment s_i

s_i^p : normalised bag of posters counting all the people mentioned in the posts and the posters themselves in a segment

New Stopping Criteria

- We update the stopping criteria for the new formulation as follows:

$$SC = w_1 * I(R, S) / I(R, C) + w_2 * (1 - G(S) / G_{max}) + w_3 * H(S) / H_{max}$$

where,

$$G(s) = \sum_{s_i \in S} c_{b_i}^t - c_{a_i}^t$$

$$H(S) = \sum_{i=1}^{|S|} \|s_i^p - s_{i+1}^p\|$$

- In SC:
 - $I(R, S) / I(R, C)$ computes the fraction of information contained in S about R, normalized by the information contained in C about R
 - $G(S) / G_{max}$ computes total segment duration normalized by total duration of chat text sequence
 - $H(S) / H_{max}$ computes normalized sum of inter segment distances in terms of poster information
- Value of second and third term decreases with cardinality of S

Datasets

- We collected chat data from two forums for our experiments:
 - Slack (public data)
 - Fresco (a proprietary platform deployed inside our organization)
- We have manually annotated them for the text segmentation task for testing the performance of our algorithm.
- The collected raw data was in the form of threads, which was later divided into segments.
- Further, we have created multiple documents where each document contains N continuous segments from the original threads where N was selected randomly between 5 and 15. (Similar to Choi. 2000)
- 60% of these documents were used for tuning hyperparameters which include weights (w_1, w_2, w_3), θ , and β ; and the remaining were used for testing.

Data Statistics

	Slack	Fresco
#Posts	9000	5000
#Segments	900	800
#Documents	73	73

Normalized frequency distribution of the segment length of the two chat datasets. Clearly, segments of Fresco are smaller.

Cumulative distribution of the vocabulary of the chat dataset compared with normal text dataset used by Choi.

Evaluation metric for segmentation

- We use the widely used metric (for evaluating segmentation) $P_k(\text{ref}, \text{hyp})$ which is defined as [5]:
 - **The probability that a randomly chosen pair of sentences k sentences apart is inconsistently classified i.e for one segmentation, the pair lie in the same segment while for the other it lies in different segments.**

- **A sliding window of fixed size k (half of the average of length of all the segments in the document) slides over the entire document from top to bottom.**
- **Both inter and intrasegment errors (miss and false alarm) for all posts k apart is calculated by comparing inferred and annotated boundaries.**
- **Low value of P_k indicates good performance.**

Results (in P_k)

Methods	Slack	Fresco	
<i>Random</i>	60.6	54	▶ Inserting boundaries at random.
<i>No-Boundary</i>	36.76	45	▶ Inserting no boundaries.
<i>Average Time</i>	32	35	▶ Boundaries are inserted after a fixed time. This time is calculated from a separate portion of the annotated dataset.
<i>C-99^[5]</i>	35.18	37.75	▶ The classic text segmentation algorithm.
<i>Dynamic Prog.^[6]</i>	28.7	35	▶ The dynamic programming algorithm proposed in [6] is used.
<i>Encoder-Decoder Dist.</i>	29	38	▶ A seq2seq RNN is trained to get a dense representation of posts. Agglomerative merging is done then based on Euc. distance
<i>LDA-Distance^[7]</i>	36	44	▶ Representations come from a topic model having 100 topics.
IB-Variants:			
<i>Text (only IB)</i>	33	42	
<i>TimeDiff</i>	26.75	34.25	
<i>Poster</i>	34.52	41.50	
<i>Text+TimeDiff</i>	26.47	34.68	
<i>Text+Poster</i>	28.57	38.21	
<i>Text+TimeDiff+Poster</i>	25.47	34.80	

[5] Advances in domain independent linear text segmentation (Choi 2000)

[6] Linear Text Segmentation using a Dynamic Programming Algorithm (Kehagias et al. 2003)

[7] Latent dirichlet allocation (Blei et al. 2003)

Quantitative Analysis

- For Slack dataset, 4 different variants of the proposed IB based method achieve higher performance than others.
- In case of Fresco dataset, different variants of the proposed method achieve superior performance but not as significantly in terms of absolute P_k value, as they do for the Slack dataset.
 - We hypothesize that such a behaviour is potentially because of the lesser value of posts per segment for Fresco ($5000/800=6.25$) in comparison to Slack ($9000/900=10$).
 - Also, note that just the time clue in IB framework performs best on Fresco dataset indicating that the relative importance of time clue will be higher for a dataset with smaller lengths of segments.
 - This can be seen from the normalized frequency distribution of both datasets.

Qualitative Analysis

— Average Time
— IB: TimeDiff
— IB: Text + TimeDiff + Poster

(b)

Effect of Parameters

$\frac{P_k}{v/s \beta}$

- β represents a trade-off between the compression and preserved information.
- As β does not lie on any extremity, it indicates its importance in the IB objective.

Effect of Parameters

$\frac{P_k}{v/s \theta}$

- Initially, the average value of P_k decreases as more coherent posts are merged.
- After reaching a minimum, it starts increasing potentially due to merging of more dissimilar posts.

Future Work

- It would be interesting to explore some deep learning methods applied to the task of chat text segmentation.
- In future, it will be interesting to investigate the possibility of incorporating semantic word embeddings in the proposed IB method.
- Major research needs to be conducted to tackle low frequency/out of vocabulary words in the context of online chats.

Thank You!
